<sup>2</sup>Department of Agronomy, Faculty of Agriculture, Bangabandhu Sheikh Mujibur Rahman Agricultural University, Gazipur, Bangladesh

**Abstract.** One hundred and seventy-five soybean genotypes were screened for their resistance against four major soil-borne fungal diseases i.e *Fusarium* wilt (*Fusarium oxysporum*), charcoal rot (*Macrophomina phaseolina*), *Rhizoctonia* dry root rot (*Rhizoctonia solani*) and collar rot (*Sclerotium rolfsii*) of soybean under field condition of Bangladesh. Among the 175 screened genotypes, only eight genotypes namely G00005, G00389, G0056, G00168, G00013, G00021, G00149 and G00322 were not affected with seedling mortality diseases. On the contrary, total 16, 48, 101 and 162 genotypes at the seedling stage were completely free from the attack of *F. oxysporum*, *M. phaseolina*, *S. rolfsii*, and *R. solani*, respectively. Only two genotypes namely AGS-129 and G00056 were found to be resistant at 0-5 scale against all the different soil-borne pathogens. A total of 38, 21, 96 and 18 genotypes were found to be highly susceptible, susceptible, moderately susceptible and moderately resistant against the different pathogens.

**Keywords:** Soybean genotypes, *F. oxysporum*, *M. phaseolina*, *R. solani*, *S. rolfsii*.

### 1. Introduction

Soybean (*Glycine max* L.) belongs to the family leguminosae is gaining important position as grain legume in the agriculture of sub-tropical countries including Srilanka, Thailand, and Bangladesh. It is also called a miracle golden bean because of its nutritive value, especially as a substitute of protein. It accounts for approximately 50% of the total production of oil seed crops in the world (Fehr, 1989). The average soybean yield in the world is about 2.93 t ha<sup>-1</sup> (Langemeier, 2016) while it is only 1.83 t ha<sup>-1</sup> and occupies around 50,202 ha cultivable land in Bangladesh (Anon, 2017). Several factors attributes for low production of soybean in Bangladesh. Among them soil-borne fungal diseases play a vital role to hamper the yield production at field soil. More than 100 pathogens are known to affect soybean crop; of which 66 fungi, 6 bacteria, 8 viruses and 7 nematodes are responsible for devastating infestation (Sinclair, 1978).

The soil borne fungi survive longer period of time in soil, plant debris and can cause devastating diseases i.e *Rhizoctonia* root rot (*Rhizoctonia solani*), collar rot (*Sclerotium rolfsii*), charcoal rot (*Macrophomina phaseolina*), *Fusarium* root rot

(*Fusarium* spp.), *Phytophthora* root rot (*Phytophthora sojae*) and *Pythium* root rot, (*Pythium* spp.) which ultimately hampered the crop yield production (Hartman *et al.*, 1999). Among the different diseases soybean suffers significantly damage from *Fusarium* wilt, charcoal rot, *Rhizoctonia* dry root rot and collar rot diseases. *Fusarium* wilt caused by *F. oxysporum* is one of the most destructive disease of the crop and it's a very common soil-borne fungus throughout the world. According to the Sinclair and Blackman (1986), *F. oxysporum* can reduce the average yield of soybean up to 59%. Charcoal rot of soybean is caused by *M. phaseolina* which is a necrotrophic phytopathogen with a wide host range including more than 500 cultivated and wild plant species belonging to more than 75 families (Khan, 2007; Salik, 2007). Under the favorable conditions, it causes seedling damping-off and at the mature stage, also can infect the pod with the formation of microsclerotia or pycnidia. This pathogen can sever yield losses and it's up to 50% have been reported in the Brazil (Ferreira *et al.*, 1979). *Rhizoctonia solani* causing dry root rot of soybean normally affects during the early growth stage affecting 50% crop yield and 40% yield loss. It is a very common soil-borne fungi which is distributed all over the worldwide with great diversity of different host plants such as bean, peanut, soybean, cucumber, papaya, eggplant, corn etc. (Ogoshiand & Ui, 1983). According to the Chang *et al.* (2018), *R. solani* caused a loss of 48% in stand establishment and 52% in soybean seed yield. The foot and root rot disease of seedling which is incited by *Sclerotium rolfsii*. It is also a soil borne pathogen with wide host range and almost worldwide distribution (Bag & Sinha, 1997; Singh *et al.*, 1998). *S. rolfsii* is the most destructive pathogenic fungus, which attacks the crop at any stage of growth (Punja, 1985). The *S. rolfsii* causes 25-50% loss through infection of seedlings and the annual yield losses by disease in soybean have been reported 10-30% (Hartman *et al.*, 1999).

Sustainable disease management method should be developed against the soil-borne pathogens for increasing the yield of soybean. But these soil-borne pathogens are difficult to control because of their persistency in soil and wide host range. Some chemicals are effective in controlling but these are expensive and not environmentally safe (Abdel-Monaim *et al.*, 2011). Although, chemical compounds have been used as seed treating fungicide and sometimes effective to control but misuse in their application has favored the development of pathogen resistant against fungicides and polluted the environment. As a result, imbalance the ecological system of the planet. Among the different disease control methods, the host resistance is one of the best sustainable method to minimize the disease economically and ecofriendly. Considering this fact, the present experiment was conducted with a view to screening soybean resistance genotypes against *F. oxysporum*, *M. phaseolina*, *R. solani*, and *S. rolfsii* at field soil.

## 2. Materials and methods

### 2.1. Experimental site and design

The field experiment was conducted at the research field of Bangabandhu Sheikh Mujibur Rahman Agricultural University, Gazipur-1706, Bangladesh. The experiment was laid out in the Randomized Complete Block Design (RCBD) with 3 replications. After land preparation the whole experimental area was divided into 3 blocks, representing 3 replications. The unit plot was 3.0 m × 1.5 m in size, distance between block to block was 1.0 m and that of plot to plot in a block was 0.50 m. Drains

were made surrounding the each unit plots and the excavated soil was used for raising plots 15 cm high from the soil surface.

### **2.2. Soybean genotypes**

A total of 175 soybean genotypes were collected from the department of Agronomy, Bangabandhu Sheikh Mujibur Rahman Agricultural University, Bangladesh (Table 1). The genotypes accession number were denoted by the chronological numerical number from 1 to 176 where numerical serial number 121 was absent.

### **2.3. Sowing and intercultural operations**

Seeds of each soybean genotype were sown in lines uniformly by hand and maintained row to row distance of 30 cm, depth of 2 cm for easy emergence and covered with pulverized soil. Weeding, mulching and irrigation were done in the experimental field whenever it was necessary.

### **2.4. Data recording**

The data were collected from the growing to harvesting stage of the crop very carefully. Prevalence of diseases was evaluated for detecting field resistance of these soybean genotypes. Data on seedling emergence were recorded at 15 days after sowing. Data on the seedling mortality of soybean genotypes due to soil-borne diseases were recorded at seedling stage (Up to 30 Days After Sowing). Selected disease development data were taken at growing stage (30-70 DAS), reproductive stage (70-100 DAS), and also at harvesting stage. The severity of different diseases was expressed in percentage based on number of total seedlings recorded on 15 days after sowing until harvest of the crop. The pathogens associated with wilt, charcoal rot, dry root rot, stem rot/ collar rot, and damping off were collected, isolated, and identified in *in-vitro* condition according to standard procedure as described by Mian (1995), Barnett and Hunter (1972). The genotypes were rated in five categories i.e resistance, moderately resistance, moderately susceptible, susceptible, and highly susceptibility on the basis of disease incidence with partially following the 0-5 scale suggested by Mian (1995). The diseases incidence were measured by number of infected plant divided by total plant and converted to percentage.

Rating	Category	Reaction type	% seedling mortality
1	R	Resistance	0.0 - 5.0
2	MR	Moderately resistance	5.1 - 10.0
3	MS	Moderately susceptible	10.1 - 15.0
4	S	Susceptible	15.1 - 20.0
5	HS	Highly Susceptible	>20.0

The disease incidence was assessed by the following formula (Rahman *et al.*, 2013).

$$\text{Disease incidence (\%)} = \frac{\text{Number of infected plants}}{\text{Total number of plants assessed}} \times 100$$

### **2.5. Data calculation**

Data were analyzed by using SPSS computer program.

### 3. Results

The characteristics symptoms of the diseases were keenly observed during growing season of the crop for confirmation of preselecting diseases. The symptom of the *Fusarium* wilt disease of soybean were found that few seedlings died before emerging. The diseased seedlings was necrotize and rot in the soil. The emerged seedlings were stunted in growth. The cotyledons were chlorotic, later become necrotic and decay. The diseased seedlings were wilted and dried up. The typical signs of the older plant was leaf chlorosis. The roots became necrotic and rotten. After cross-section of the stem the necrosis was observed inside the stem cells. At the mature stage, pods were poorly developed and dried. The seeds were smaller, oblong, shriveled and light in color (Plate I). According to Xue *et al.* (2007) the initial symptoms of *Fusarium* wilt disease are water soaked lesions with dark brown to pink discoloration around the infection area.

The symptoms of charcoal rot was observed brown lesions formed on the hypocotyl of emerging seedlings. Infected petioles, leaflets and twig of the plant were appeared small and ultimately wilted finally turned brown in color. The lower stem and taproot became dotted with light gray in color. Small black specks were formed under the epidermis and inside the lower stem and taproot. After cross section of the infected root and stem the reddish-brown discoloration was prominently found. At the mature stage huge black pycnidia were produced on infected stem, petioles and pod as a result seeds became shriveled and discolored (Plate I). Gupta and Chauhan (2005), Short *et al.* (1978) reported that, charcoal rot symptoms include yellow leaves, reduced vigor, brown to red discoloration on roots and stems, and a general wilting also.

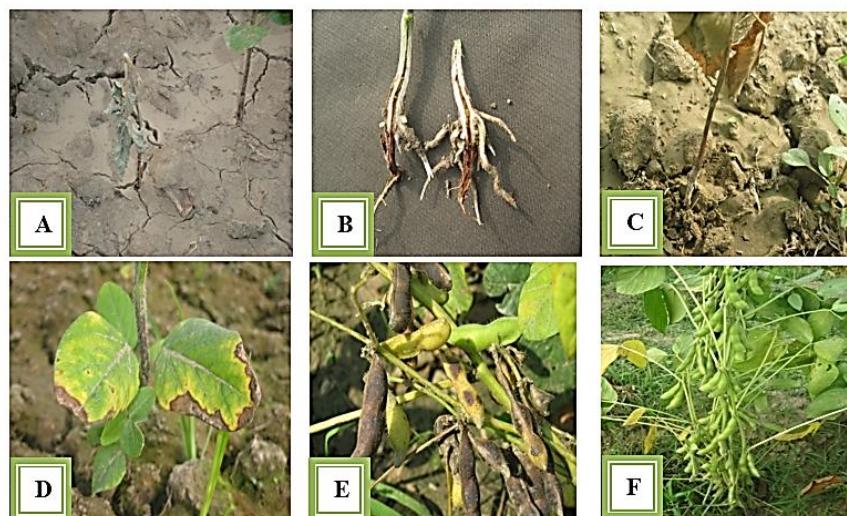

Plate I. Diseases of soybean in the field: A-B: *Fusarium* wilt caused by *Fusarium oxysporum*, C-E: Charcoal rot of soybean caused by *Macrophomina phaseolina* and F: Healthy soybean plant with pods

The disease symptoms of *Rhizoctonia* dry root rot were found rusty-brown, sunken lesions form on hypocotyls of young seedlings, stems and roots at collar region. Damping-off occurs when germinating seedlings were infected prior to emergence. The lateral roots of the plant were decayed as a results when pulled the seedling it was uprooted very easily. The older plants was appeared growth stunted, yellowish, and

wilted. The pathogen was girdled the stem with their mycelium and developed crusty minutes sclerotial. After cross section of the infected root and stem the brown discoloration line was appeared (Plate II). According to the Takehara *et al.* (2016) web-like mycelia developed on wet plant parts and pods and finally rotten in plants with severe symptoms.

First initial symptoms of the collar rot disease of soybean in the field was observed at or just below the soil surface that is collar region of the plant. The white color mycelium mat was found on stem bases and the soil surface around infected plants. This mycelial mat was spread several centimeters up the stem above the ground. In the infected parts of the plant was appeared light brown depressed lesions, which quickly turned darken and enlarge. Gradually the plant became yellowing or wilting. Plenty white (immature) tan to brown, spherical, mustard seed like sclerotia were formed on infested plant material and around the rhizosphereregion (Plate II). Wilson (1953) described that, the plant stem near the soil surface is covered by mycelium, it is one of the most prominent symptom of the collar rot disease.

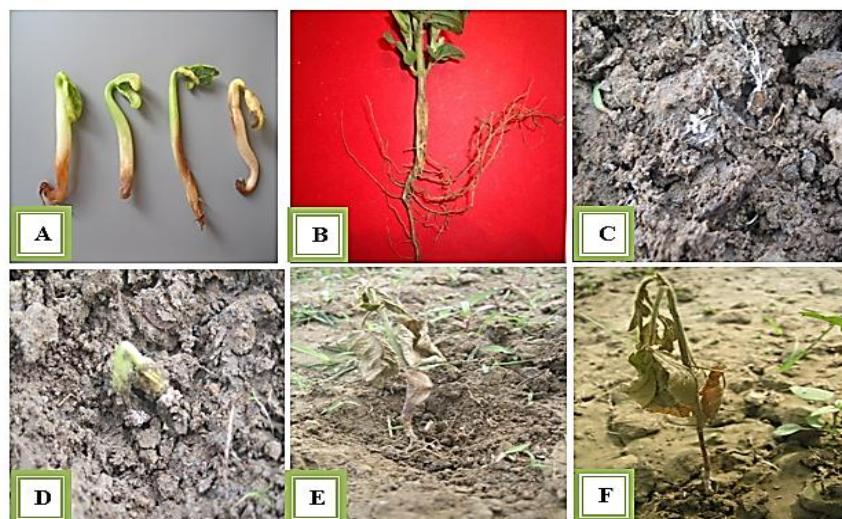

Plate II. Diseases of soybean in the field: A–B: *Rhizoctonia* Dry root rot caused by *Rhizoctonia solani*, C-D: Pre and post emergence seedling mortality caused by *Sclerotium rolfsii* and E-F: Collar rot of soybean caused by *S. rolfsii*.

Characteristic symptoms of those diseases were observed of soybean germplasms and to confirm the causal agents of the diseases associated soil-borne fungal pathogens were isolated regularly following tissue planting method as described earlier. Soil- borne pathogens namely *F. oxysporum*, *M. phaseolina*, *R. solani* and *S. rolfsii* were found to be responsible for the seedling mortality of soybean genotypes. The highest 55.55% seedling mortality was observed in the genotype G00046 followed by 47.04% seedling mortality in the genotype G00053 (Table 5). Only eight genotypes namely G00005, G00389, G00056, G00168, G00013, G00021, G00149, and G00322 were not affected with post-emergence damping off or seedling mortality at the seedling stage. At the seedling stage 16, 48, 101 and 162 genotypes were completely free from the attack of *S. rolfsii* *R. solani*, *F. oxysporum*, and *M. phaseolina*, respectively (Table 3). The result reveals that *S. rolfsii* was appeared to be most serious at the seedling stage of the crop.

The tested 175 genotypes, only two genotypes namely AGS-129 and G00056 were found to be resistance where no disease incidence was observed in AGS-129 from growing stage to harvesting stage and the genotype G00056 was only infected with *M. phaseolina* at the mature stage (Table 2). Among the evaluated soybean genotypes the lowest 4.76% disease incidence was observed with AGS-129 and G00056. On the contrary, the highest 85.68% disease incidence from seedling to harvesting stage was recorded with the genotype BD2329 followed by G00362, G00011, G00204, AGS403, G00053, G00069, and G00046, respectively. These genotypes were found highly susceptible against all the pathogens (Table 6). Disease reaction of all the tested genotypes were summarized in the Table 2 reveals that a total of 38, 21, 96 and 18 genotypes were found to be highly susceptible, susceptible, moderately susceptible and moderately resistant, respectively.

The screened genotypes are not equally susceptible to all the pathogens. A total of 142, 108, 92 and 78 genotypes were not infected by *F. oxysporum*, *R. solani*, *S. rolfsii* and *M. phaseolina*, respectively at the growing stage to maturity stage (Table 3). Most of the genotypes were not resistant against all the pathogen but were found resistant against individual pathogen.

#### 4. Discussion

The response of 175 soybean genotypes under uninoculated natural field condition for their resistance against *F. oxysporum*, *M. phaseolina*, *R. solani* and *S. rolfsii* was evaluated. All the soybean genotypes are categorized in 0-5 scale. Characteristic symptoms of the diseases were observed during all the growth stages of soybean germplasms. To confirm the causal agents of the diseases associated soil-borne fungal pathogens were isolated regularly following tissue planting method. Soil- borne pathogens namely *F. oxysporum*, *M. phaseolina*, *R. solani* and *S. rolfsii*, were found to be responsible for the seedling mortality of soybean genotypes. The highest 55.55% seedling mortality was observed in the genotype G00046 followed by 47.04% seedling mortality in the genotype G00053. Only eight genotypes namely G00005, G00389, G00056, G00168, G00013, G00021, G00149 and G00322 were not affected with post-emergence damping off or seedling mortality at the seedling stage. At the seedling stage only 16 genotypes were completely free from the attack of *S. rolfsii*, 48, 101 and 162 genotypes were completely free from the attack of *R. solani*, *F. oxysporum* and *M. phaseolina* respectively. The result reveals that *S. rolfsii* was appeared to be most serious at the seedling stage of the crop. Among the tested 175 genotypes, only two genotypes namely AGS-129 and G00056 were found to be resistance where no disease incidence was observed in AGS-129 from growing stage to harvesting stage and the genotype G00056 was only infected with *M. phaseolina* at the mature stage. Among the evaluated soybean genotypes the lowest 4.76% disease incidence was observed with AGS-129 and G00056. On the contrary, the highest 85.68% disease incidence from seedling to harvesting stage was recorded with the genotype BD2329 followed by G00362, G00011, G00204, AGS403, G00053, G00069 and G00046 which were found highly susceptible against all the pathogens. Disease reaction of all the tested genotypes reveals that a total of 38, 21, 96 and 18 genotypes were found to be highly susceptible, susceptible, moderately susceptible and moderately resistant. The screened genotypes are not equally susceptible to all the pathogens. A total of 142, 108, 92 and 78 genotypes were not infected by *F. oxysporum*, *R. solani*, *S. rolfsii*, and *M. phaseolina*,

respectively at the growing stage to maturity stage. Most of the genotypes were not resistant against all the pathogen but were found resistant against individual pathogen. Association of these soil-borne pathogens of soybean has been also been reported by many researchers from different soybean growing countries of the world (Singh *et al.*, 1974; Sinclair, 1978; Punja, 1985; Yang *et al.*, 1988; Hartman *et al.*, 1999).

## 5. Conclusion

The present study revealed that, among the 175 tested genotypes only two genotypes namely AGS-129 and G00056 were found resistance against *Fusarium oxysporum*, *Macrophomina phaseolina*, *Rhizoctonia solani* and *Sclerotium rolfsii* where no disease incidence was observed in AGS-129 from growing stage to harvesting stage of soybean. In the meantime, a total of 38, 21, 96 and 18 genotypes were found to be highly susceptible, susceptible, moderately susceptible and moderately resistant, respectively. On the contrary, a total of 142, 108, 92 and 78 genotypes were not infected by *F. oxysporum*, *R. solani*, *S. rolfsii* and *M. phaseolina*, respectively at the growing to maturity stage of soybean. Most of the genotypes were not resistant against all tested pathogens but resistant against individual pathogen.
